Đúng

Đạt điểm 1,00 trên 1,00

Implement function

```
int foldShift(long long key, int addressSize);
int rotation(long long key, int addressSize);
```

to hashing key using Fold shift or Rotation algorithm.

Review Fold shift:

The **fold method** for constructing hash functions begins by dividing the item into equal-size pieces (the last piece may not be of equal size). These pieces are then added together to give the resulting hash value.

For example:

Test	Result
cout << rotation(600101, 2);	26

Answer: (penalty regime: 0 %)

Reset answer

```
1 int foldShift(long long key, int addressSize)
2 {
3     int sum=0;
4     string s = to_string(key), substr="";
5     int n=s.size();
6     int divi=pow(10, addressSize);
7     for (int i=0; i<n; i++) {
8         substr+=s[i];
9         if ((i+1) % addressSize == 0 || i==n-1) {
10             sum+=stoi(substr);
11             substr="";
12         }
13     }
14     return sum%divi;
15 }
16
17
18
19 int rotation(long long key, int addressSize)
20 {
21     long long remain = key%10, mul=1;
22     long long newKey = key/10;
23     while (key%mul < key) mul*=10;
24     mul/=10;
25     newKey+= remain*mul;
26     return foldShift(newKey, addressSize);
27 }
28 }
```

	Test	Expected	Got	
✓	cout << rotation(600101, 2);	26	26	✓

Passed all tests! ✓

Implement three following hashing function:

```
long int midSquare(long int seed);
long int moduloDivision(long int seed, long int mod);
long int digitExtraction(long int seed, int* extractDigits, int size);
```

Note that:

In midSquare function: we eliminate 2 last digits and get the 4 next digits.

In digitExtraction: extractDigits is a sorted array from smallest to largest index of digit in seed (index starts from 0). The array has size **size**.

For example:

Test	Result
int a[]={1,2,5}; cout << digitExtraction(122443,a,3);	223
cout <<midSquare(9452);	3403

Answer: (penalty regime: 0, 0, 0 %)

Reset answer

```
1 long int midSquare(long int seed)
2 {
3     return ((seed*seed)/100)%10000;
4 }
5 long int moduloDivision(long int seed, long int mod)
6 {
7     return seed%mod;
8 }
9 long int digitExtraction(long int seed,int* extractDigits,int size)
10 {
11     string s=to_string(seed), result="";
12     for (int i=0; i<size; i++) {
13         result+=s[extractDigits[i]];
14     }
15     return stoi(result);
16 }
17
```

	Test	Expected	Got	
✓	int a[]={1,2,5}; cout << digitExtraction(122443,a,3);	223	223	✓
✓	cout <<midSquare(9452);	3403	3403	✓

Passed all tests! ✓

Câu hỏi 3

Đúng

Đạt điểm 1,00 trên 1,00

There are n people, each person has a number between 1 and 100000 ($1 \leq n \leq 100000$). Given a number $target$. Two people can be matched as a **perfect pair** if the sum of numbers they have is equal to $target$. A person can be matched no more than 1 time.

Request: Implement function:

```
int pairMatching(vector<int>& nums, int target);
```

Where $nums$ is the list of numbers of n people, $target$ is the given number. This function returns the number of **perfect pairs** can be found from the list.

Example:

The list of numbers is {1, 3, 5, 3, 7} and $target = 6$. Therefore, the number of **perfect pairs** can be found from the list is 2 (pair (1, 5) and pair (3, 3)).

Note:

In this exercise, the libraries `iostream`, `string`, `cstring`, `climits`, `utility`, `vector`, `list`, `stack`, `queue`, `map`, `unordered_map`, `set`, `unordered_set`, `functional`, `algorithm` has been included and `namespace std` are used. You can write helper functions and classes. Importing other libraries is allowed, but not encouraged, and may result in unexpected errors.

For example:

Test	Result
<pre>vector<int>items{1, 3, 5, 3, 7}; int target = 6; cout << pairMatching(items, target);</pre>	2
<pre>int target = 6; vector<int>items{4,4,2,1,2}; cout << pairMatching(items, target);</pre>	2

Answer: (penalty regime: 0, 0, 0, 5, 10, ... %)

Reset answer

```

1  int pairMatching(vector<int>& nums, int target) {
2      unordered_map<int, int> freqMap; // Map lưu trữ tần suất của các số
3      int count = 0; // Đếm số cặp hoàn hảo
4
5      // Duyệt qua tất cả các số trong nums
6      for (int num : nums) {
7          int complement = target - num; // Tính số bổ sung để tạo thành cặp với num
8
9          // Kiểm tra nếu số bổ sung đã có trong map
10         if (freqMap[complement] > 0) {
11             count++; // Tìm thấy một cặp hoàn hảo
12             freqMap[complement]--; // Giảm tần suất của số bổ sung
13         } else {
14             freqMap[num]++; // Thêm số hiện tại vào map
15         }
16     }
17
18     return count;
19 }
```

	Test	Expected	Got	
✓	<pre>vector<int>items{1, 3, 5, 3, 7}; int target = 6; cout << pairMatching(items, target);</pre>	2	2	✓
